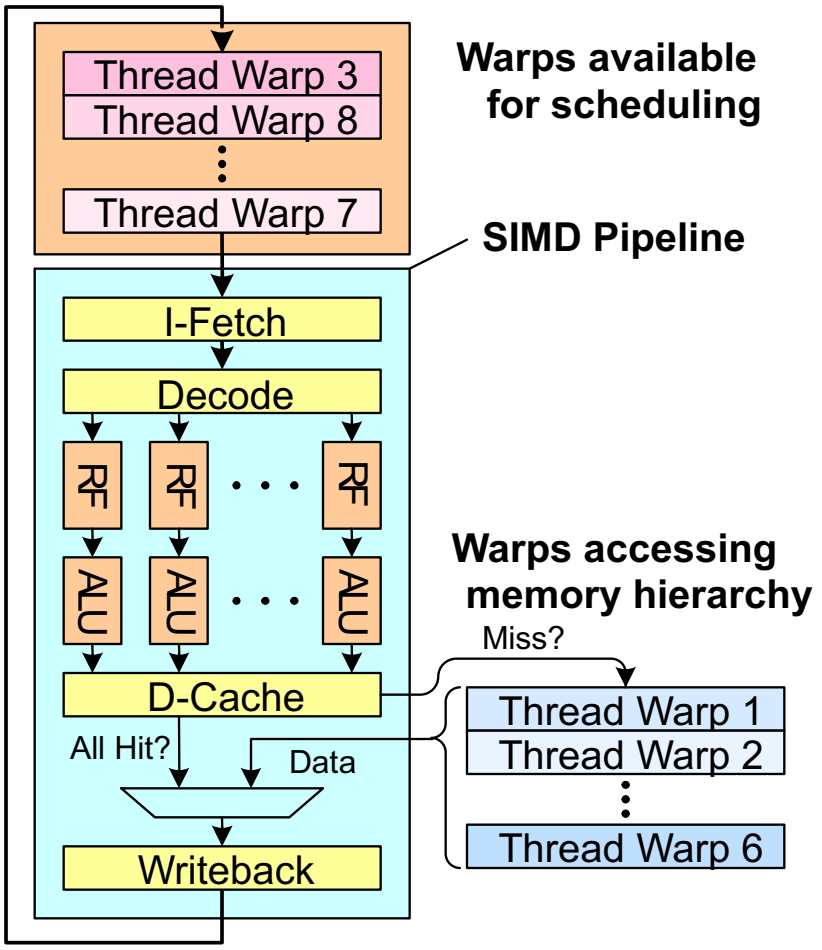
* Preliminary performance estimates

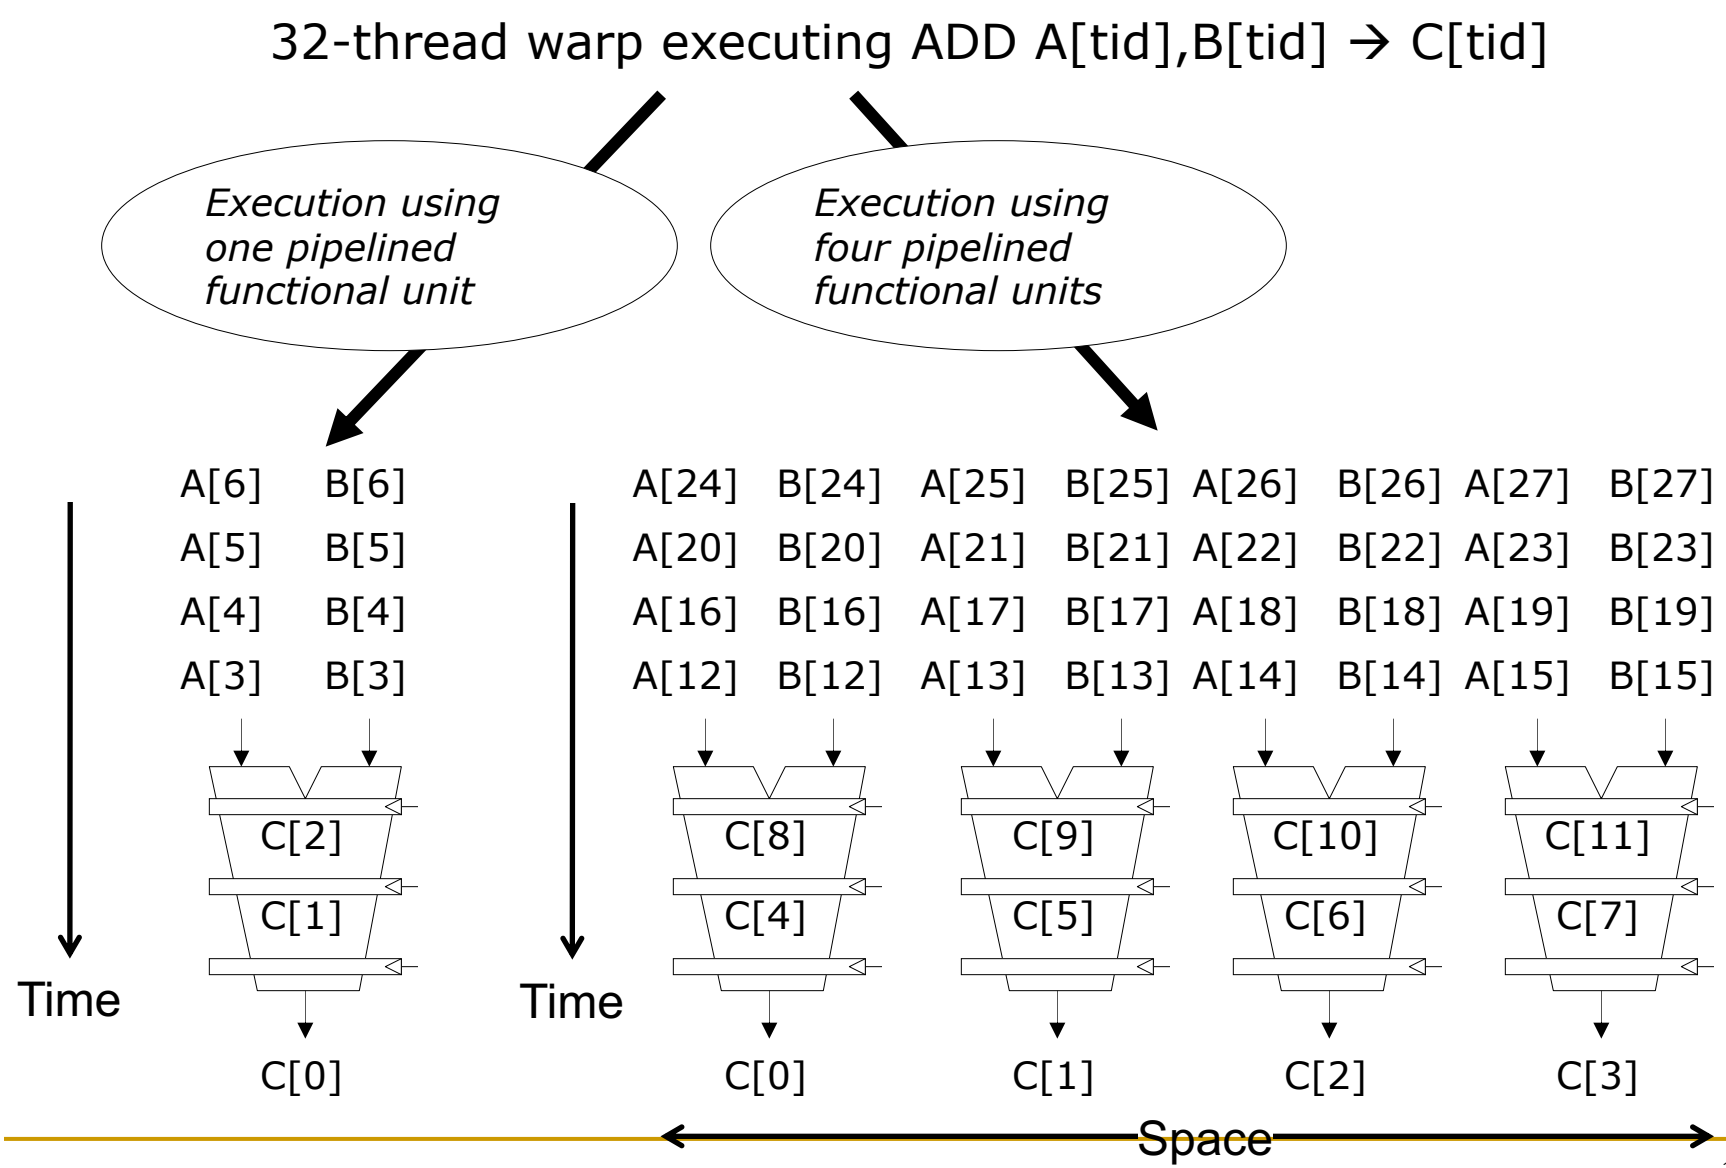
Recall: Latency Hiding via Warp-Level FGMT

- Warp: A set of threads that execute the same instruction (on different data elements)
- Fine-grained multithreading
  - One instruction per thread in pipeline at a time (No interlocking)
  - Interleave warp execution to hide latencies
- Register values of all threads stay in register file
- FGMT enables long latency tolerance
  - Millions of pixels



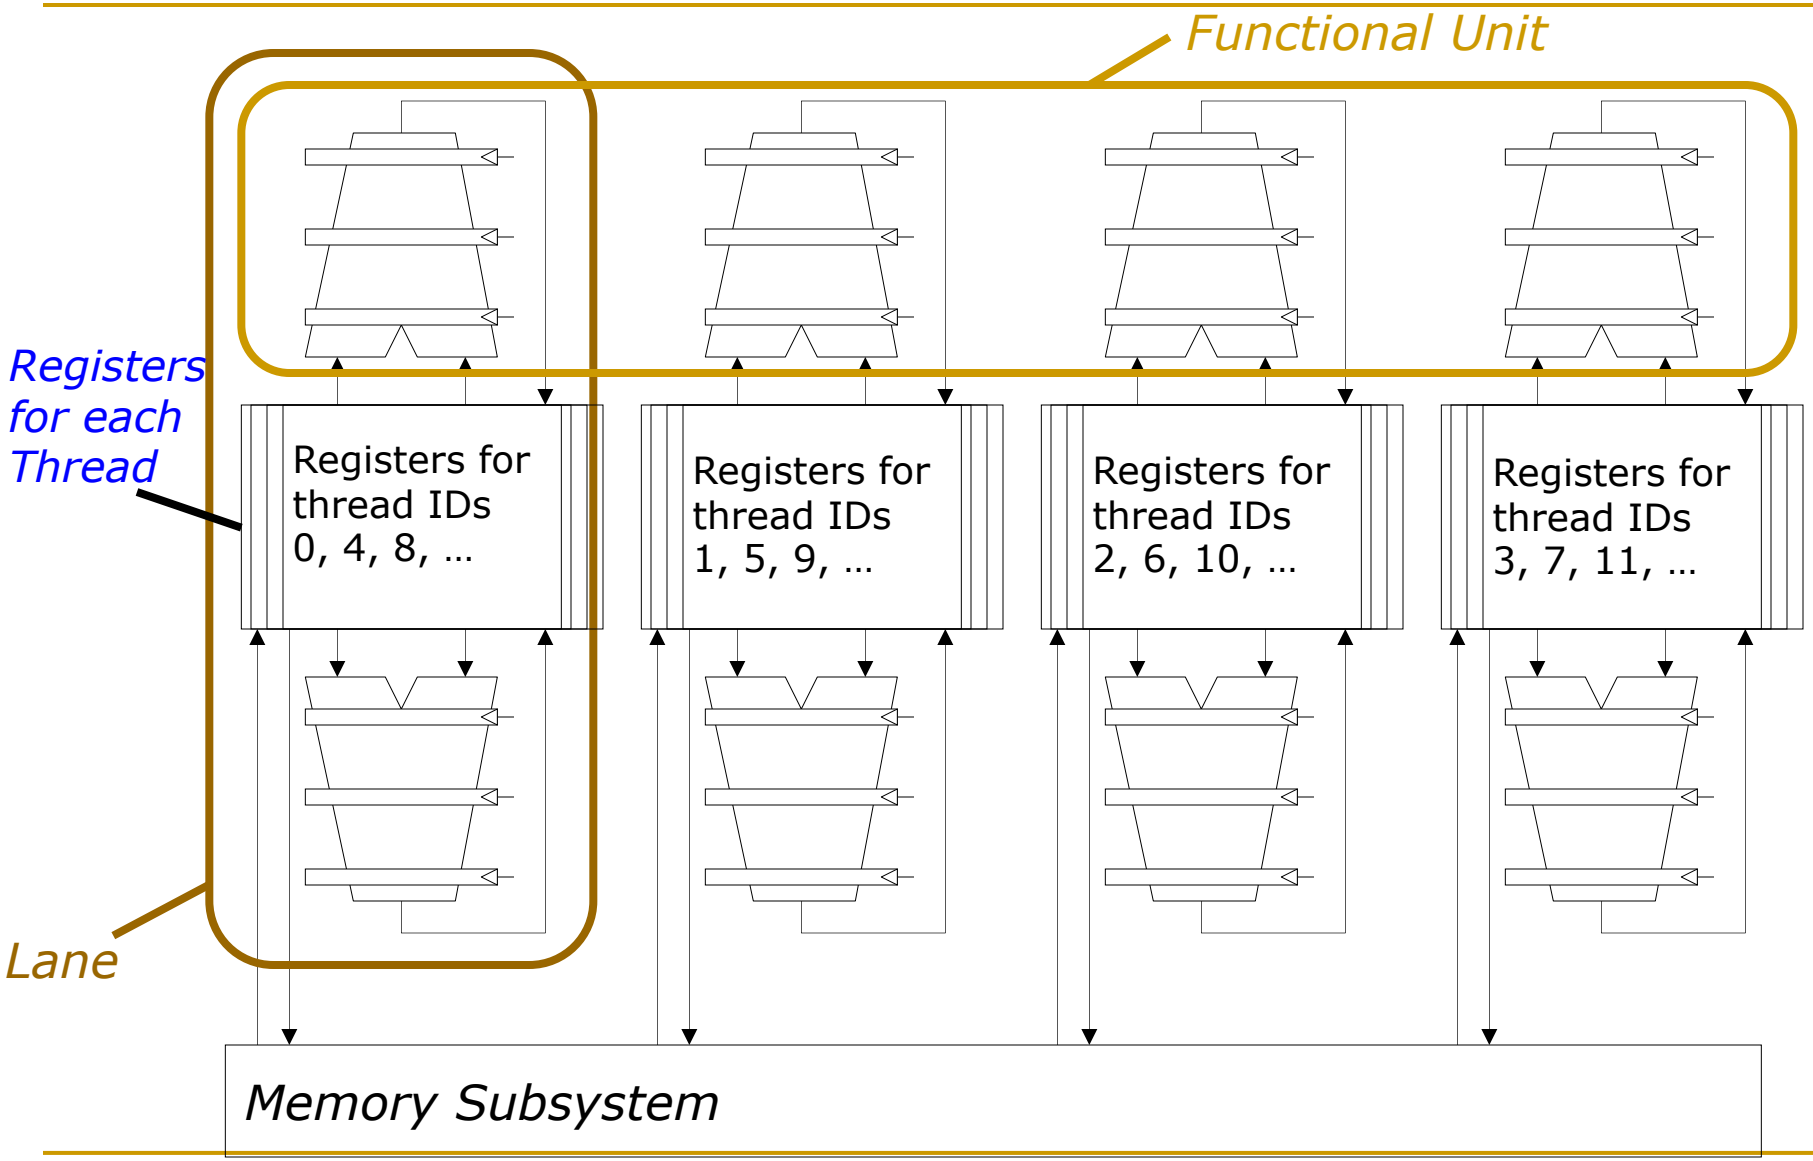
Slide credit: Tor Aamodt

Recall: Warp Execution



Slide credit: Krste Asanovic

Recall: SIMD Execution Unit Structure

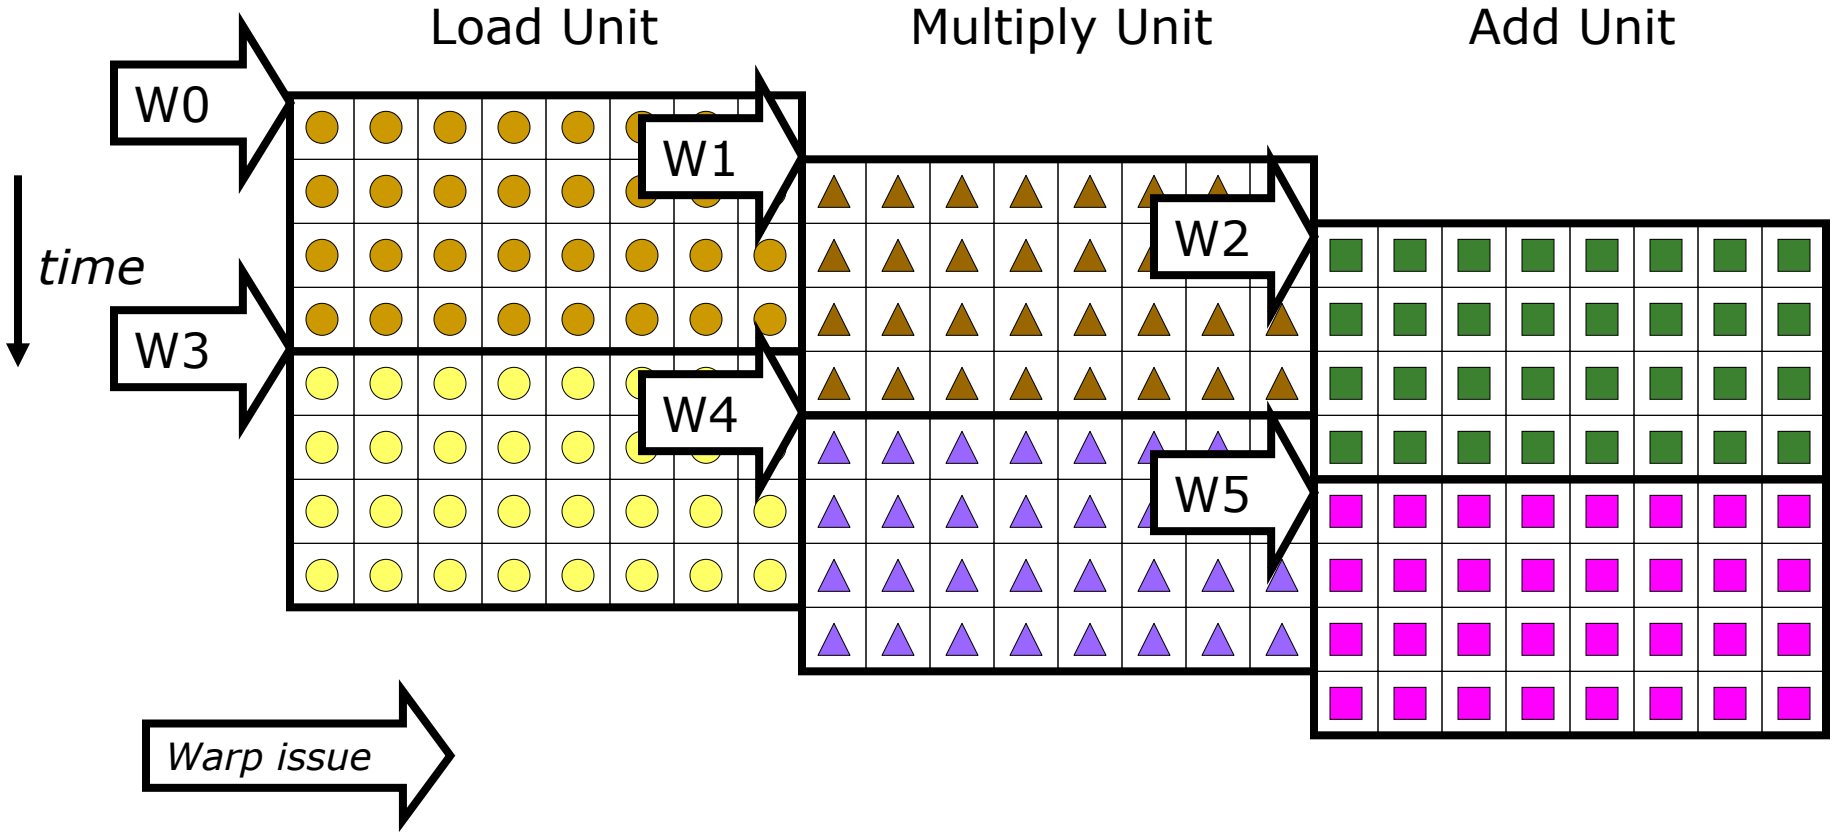


Slide credit: Krste Asanovic

Recall: Warp Instruction Level Parallelism

Can overlap execution of multiple instructions

- Example machine has 32 threads per warp and 8 lanes
- Completes 24 operations/cycle while issuing 1 warp/cycle



Slide credit: Krste Asanovic

GPU Programming

Recall: Vector Processor Disadvantages

-- Works (only) if parallelism is regular (data/SIMD parallelism)

++ Vector operations

-- Very inefficient if parallelism is irregular

-- How about searching for a key in a linked list?

To program a vector machine, the compiler or hand coder must make the data structures in the code fit nearly exactly the regular structure built into the hardware. That's hard to do in first place, and just as hard to change. One tweak, and the low-level code has to be rewritten by a very smart and dedicated programmer who knows the hardware and often the subtleties of the application area. Often the rewriting is

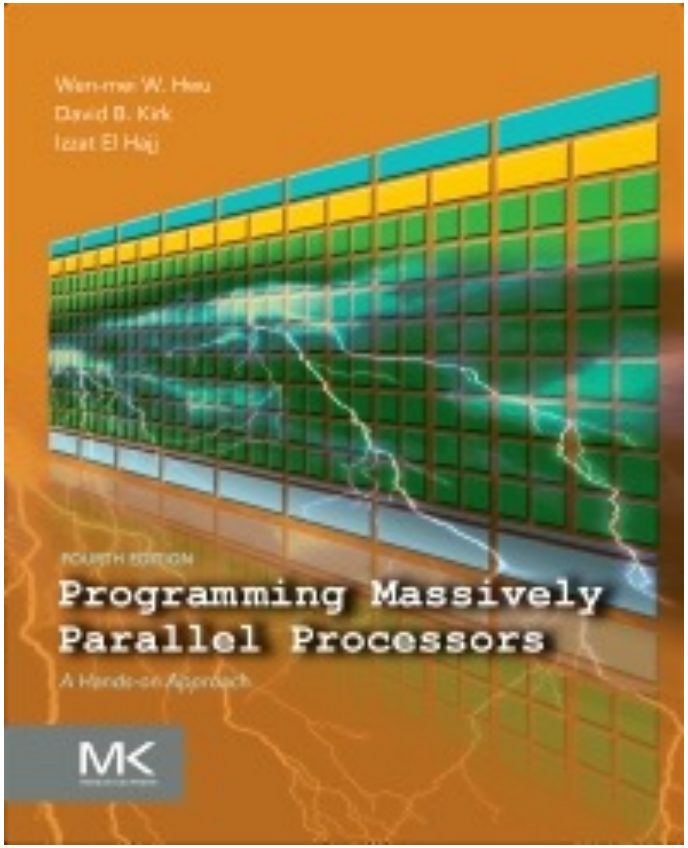
Fisher, "Very Long Instruction Word architectures and the ELI-512," ISCA 1983.

General Purpose Processing on GPU

- Easier programming of SIMD processors with SPMD
  - GPUs have democratized High Performance Computing (HPC)
  - Great FLOPS/$, massively parallel chip on a commodity PC
- Many workloads exhibit inherent parallelism
  - Matrices
  - Image processing
  - Deep neural networks
- However, this is not for free
  - New programming model
  - Algorithms need to be re-implemented and rethought
- Still some bottlenecks
  - CPU-GPU data transfers (PCIe, NVLINK)
  - DRAM memory bandwidth (GDDR5, GDDR6, HBM2, HBM3)
    - Data layout

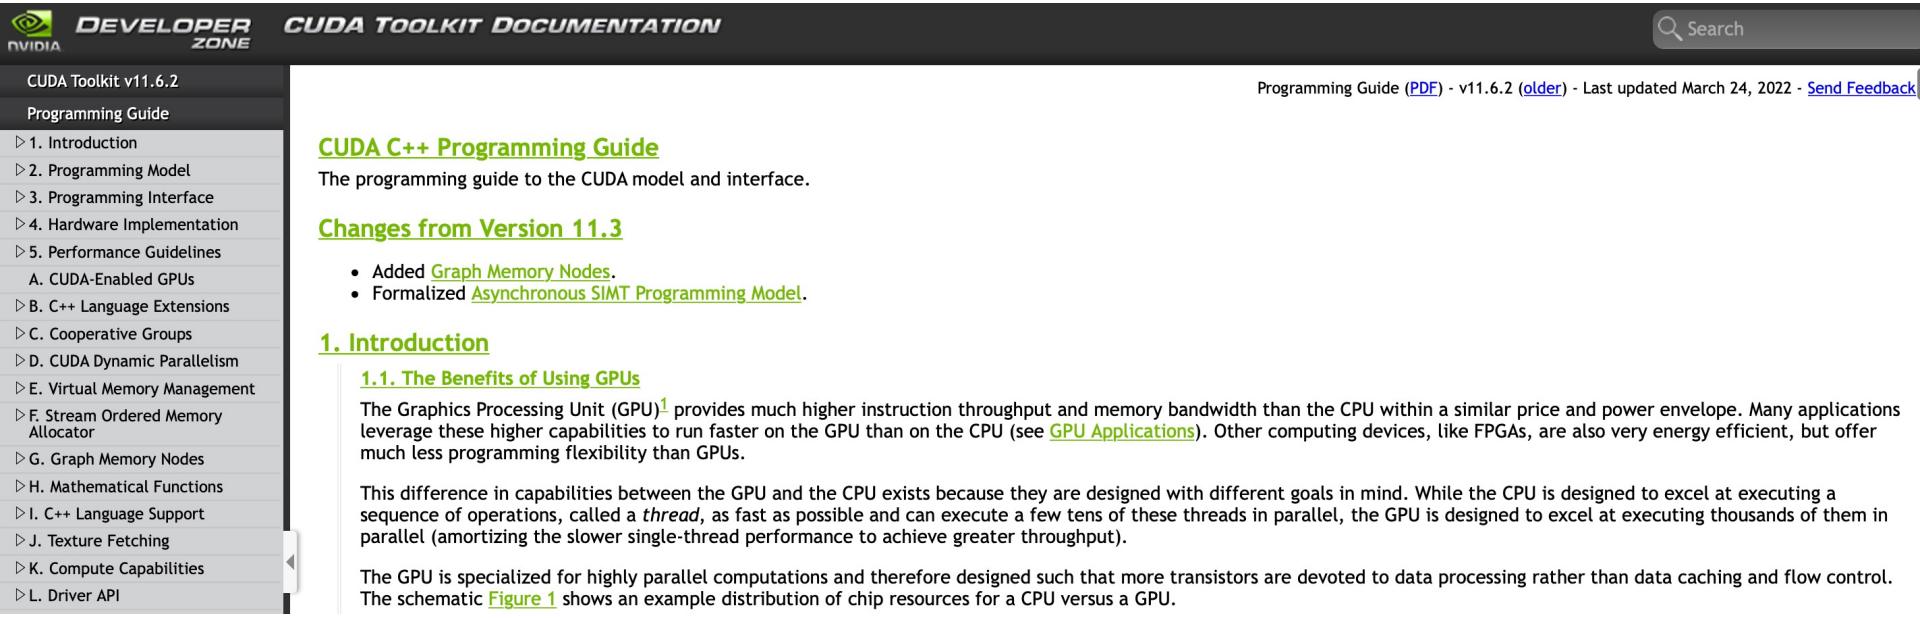
Recommended Readings (I)

- Hwu, Kirk, El Hajj , "Programming Massively Parallel Processors," Fourth Edition, 2022



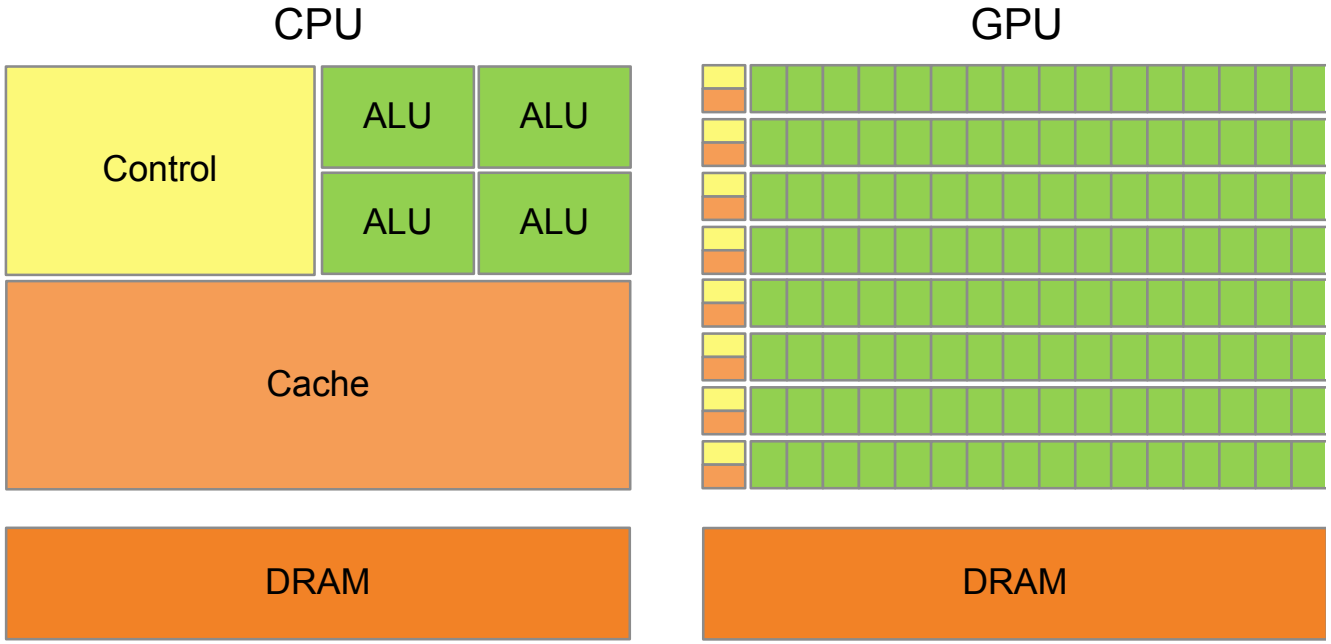
Recommended Readings (II)

- CUDA Programming Guide
  - https://docs.nvidia.com/cuda/cuda-c-programming-guide/index.html



CPU vs. GPU

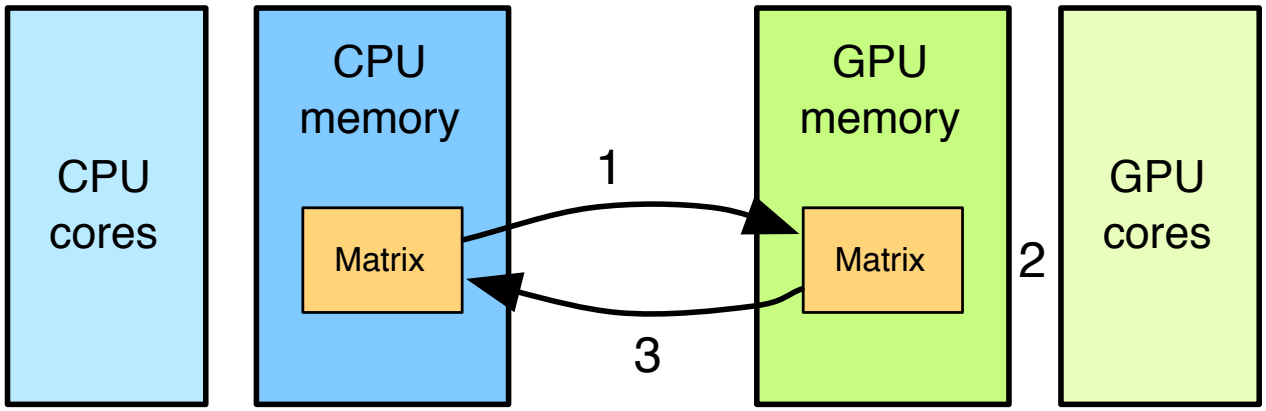
- Different design philosophies
  - CPU: A few out-of-order cores
  - GPU: Many in-order FGMT cores



Slide credit: Hwu & Kirk

GPU Computing

- Computation is offloaded to the GPU
- Three steps
  - CPU-GPU data transfer (1)
  - GPU kernel execution (2)
  - GPU-CPU data transfer (3)



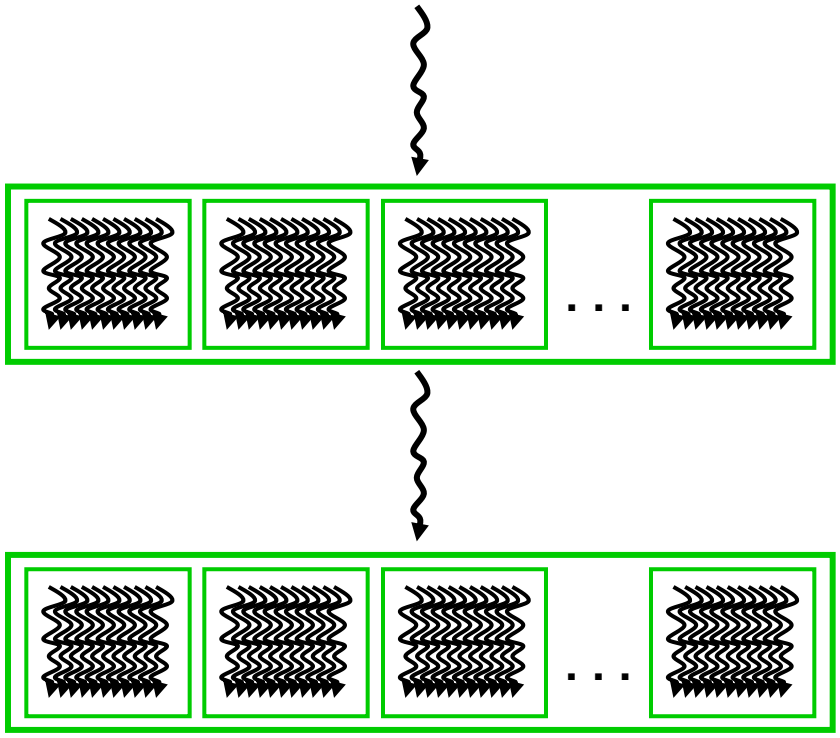
Traditional Program Structure

- CPU threads and GPU kernels
  - Sequential or modestly parallel sections on CPU
  - Massively parallel sections on GPU

Serial Code (host)

Parallel Kernel (device)

```
KernelA<<< nBlk, nThr >>>(args);
```



Serial Code (host)

Parallel Kernel (device)

```
KernelB<<< nBlk, nThr >>>(args);
```

Slide credit: Hwu & Kirk

Recall: SPMD

- Single procedure/program, multiple data
  - This is a programming model rather than computer organization
- Each processing element executes the same procedure, except on different data elements
  - Procedures can synchronize at certain points in program, e.g. barriers
- Essentially, multiple instruction streams execute the same program
  - Each program/procedure 1) works on different data, 2) can execute a different control-flow path, at run-time
  - Many scientific applications are programmed this way and run on MIMD hardware (multiprocessors)
  - Modern GPUs programmed in a similar way on a SIMD hardware

CUDA/OpenCL Programming Model

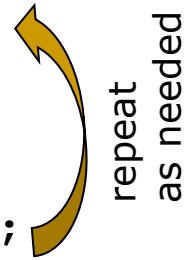
- SIMT or SPMD
- Bulk synchronous programming
  - Global (coarse-grain) synchronization between kernels
- The host (typically CPU) allocates memory, copies data, and launches kernels
- The device (typically GPU) executes kernels
  - Grid (NDRange)
  - Block (work-group)
    - Within a block, shared memory, and synchronization
  - Thread (work-item)

Traditional Program Structure in CUDA

- Function prototypes

```
float serialFunction(…);
__global__ void kernel(…);
```

- `main()`
  - 1) Allocate memory space on the device – `cudaMalloc(&d_in, bytes);`
  - 2) Transfer data from host to device – `cudaMemCpy(d_in, h_in, …);`
  - 3) Execution configuration setup: #blocks and #threads
  - 4) Kernel call – `kernel<<<execution configuration>>>(args…);`
  - 5) Transfer results from device to host – `cudaMemCpy(h_out, d_out, …);`



- Kernel – `__global__ void kernel(type args,…)`
  - Automatic variables transparently assigned to registers
  - Shared memory: `__shared__`
  - Intra-block synchronization: `__syncthreads();`

Slide credit: Hwu & Kirk

CUDA Programming Language

- Memory allocation

```
cudaMalloc((void**)&d_in, #bytes);
```

- Memory copy

```
cudaMemcpy(d_in, h_in, #bytes, cudaMemcpyHostToDevice);
```

- Kernel launch

```
kernel<<< #blocks, #threads >>>(args);
```

- Memory deallocation

```
cudaFree(d_in);
```

- Explicit synchronization

```
cudaDeviceSynchronize();
```

Host Code Example: Vector Addition

```
void vecadd(float* A, float* B, float* C, int N) {

    // Allocate GPU memory
    float *A_d, *B_d, *C_d;
    cudaMalloc((void**) &A_d, N*sizeof(float));
    cudaMalloc((void**) &B_d, N*sizeof(float));
    cudaMalloc((void**) &C_d, N*sizeof(float));

    // Copy data to GPU memory
    cudaMemcpy(A_d, A, N*sizeof(float), cudaMemcpyHostToDevice);
    cudaMemcpy(B_d, B, N*sizeof(float), cudaMemcpyHostToDevice);

    // Perform computation on GPU
    ...

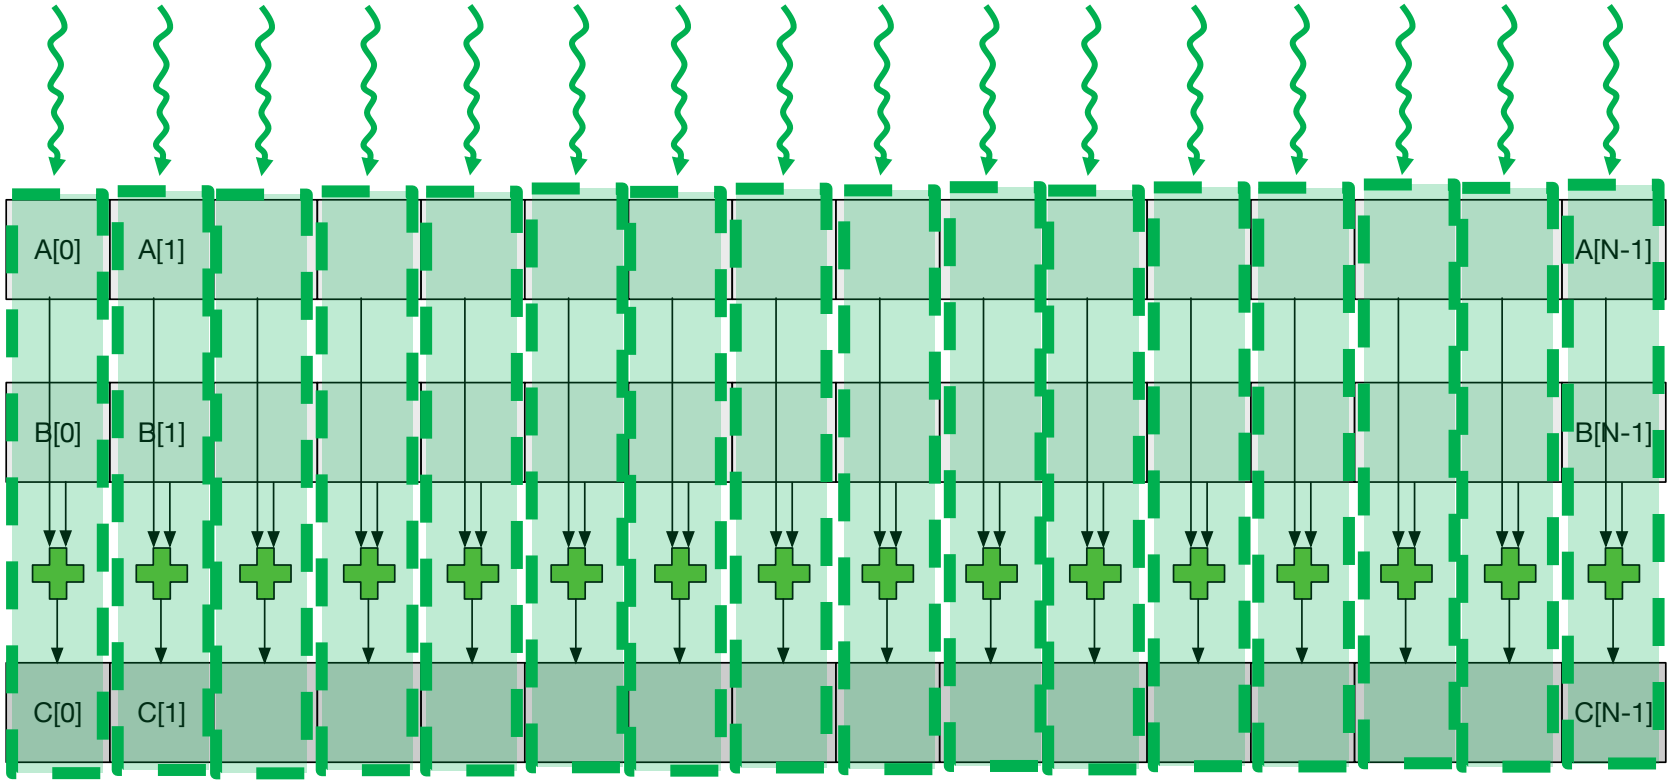
    // Copy data from GPU memory
    cudaMemcpy(C, C_d, N*sizeof(float), cudaMemcpyDeviceToHost);

    // Deallocate GPU memory
    cudaFree(A_d);
    cudaFree(B_d);
    cudaFree(C_d);
}
```

Slide credit: Izzat El Hajj

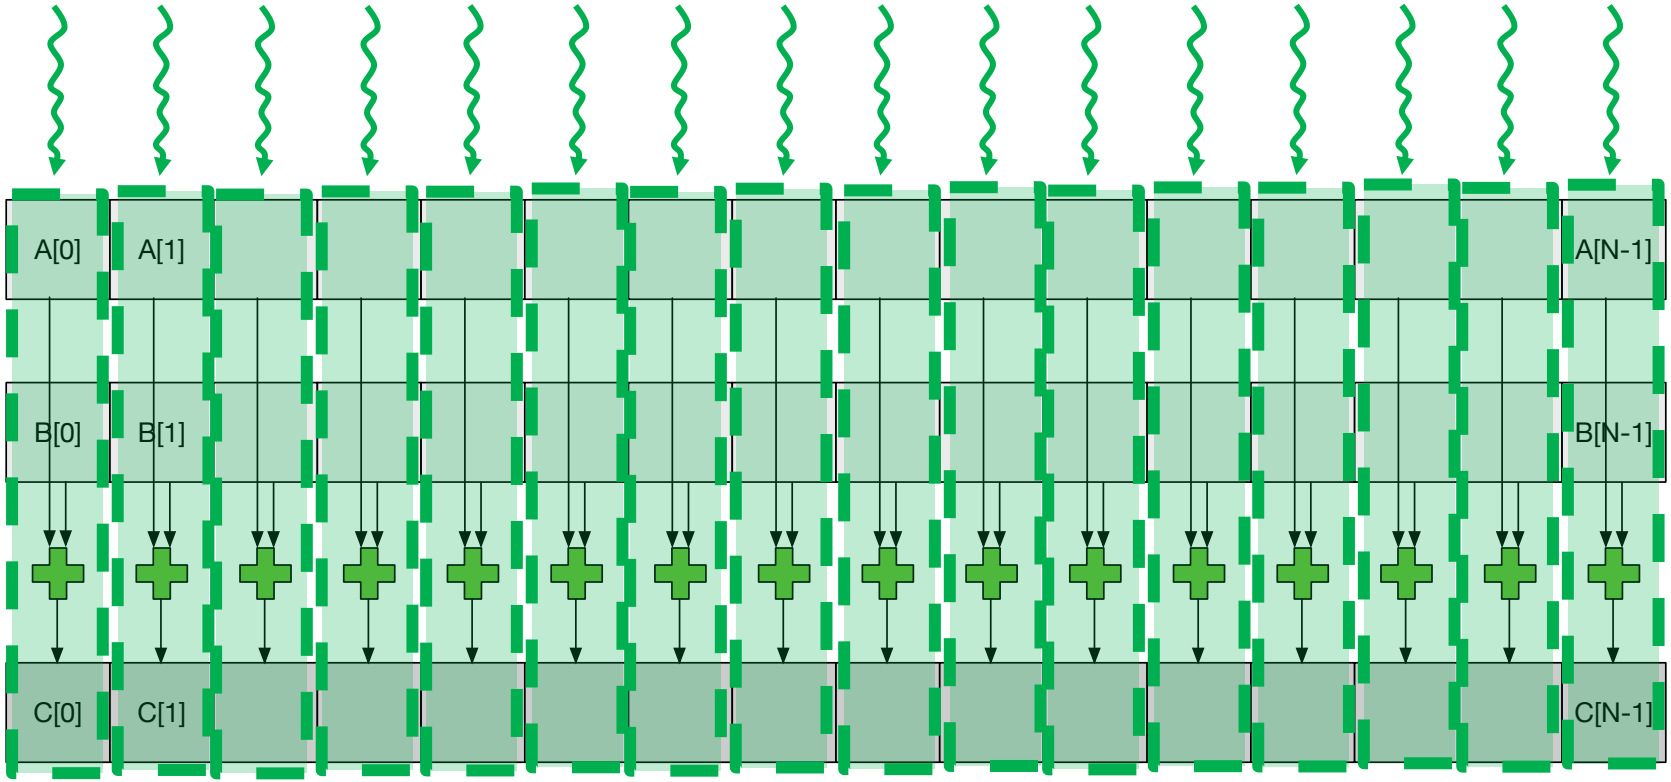
Vector Addition (I)

- Our first GPU programming example
- We assign one GPU thread to each element-wise addition



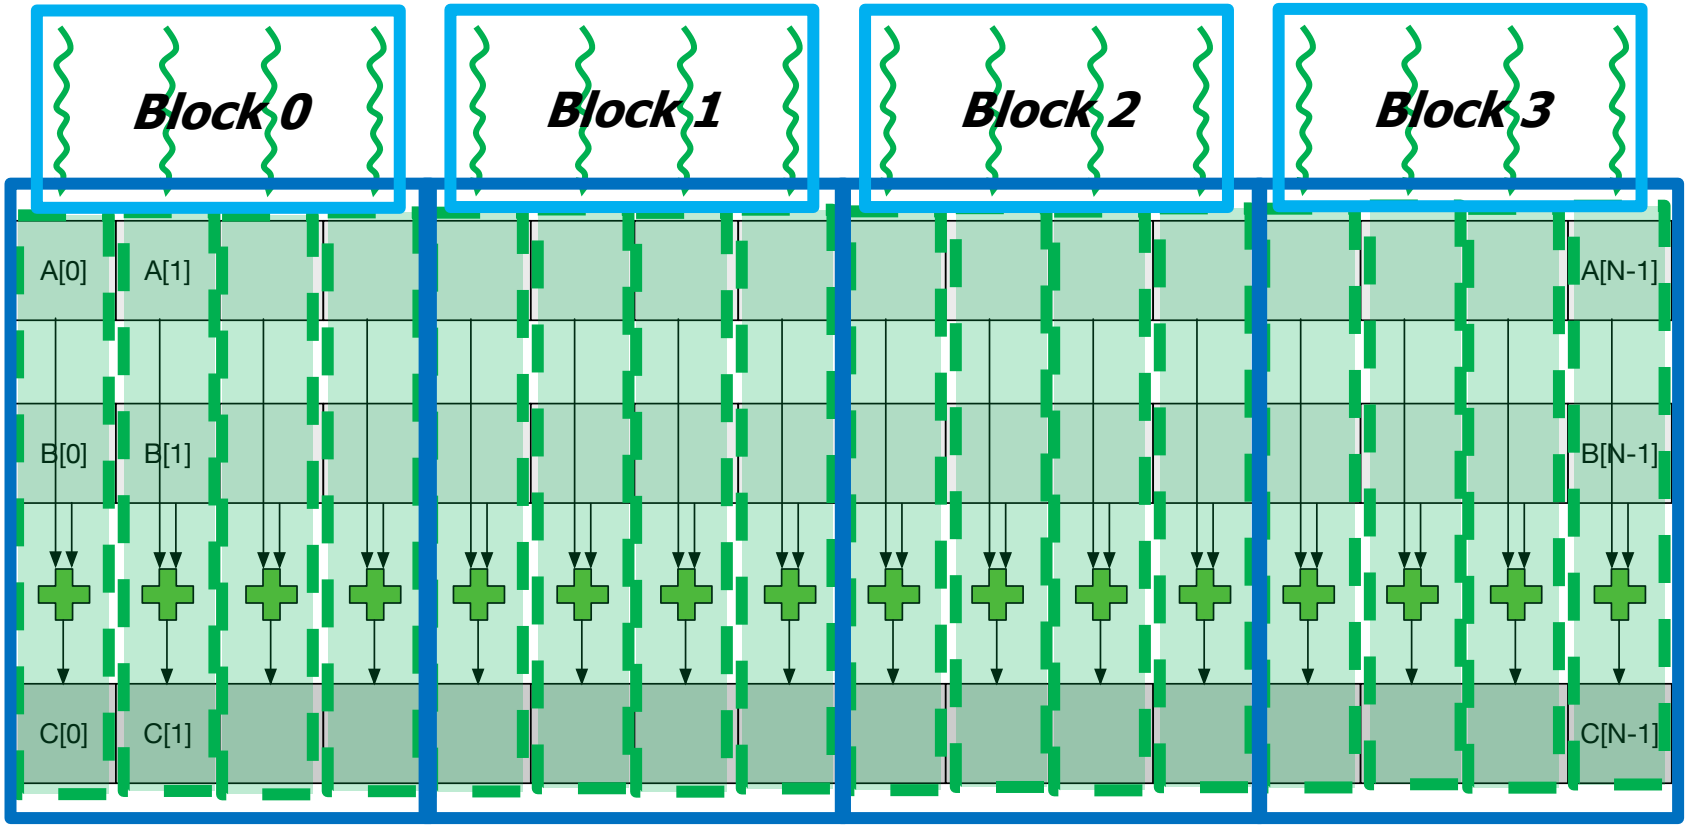
Vector Addition (II)

- The whole set of threads is called a grid
- We need a way to assign threads to GPU cores



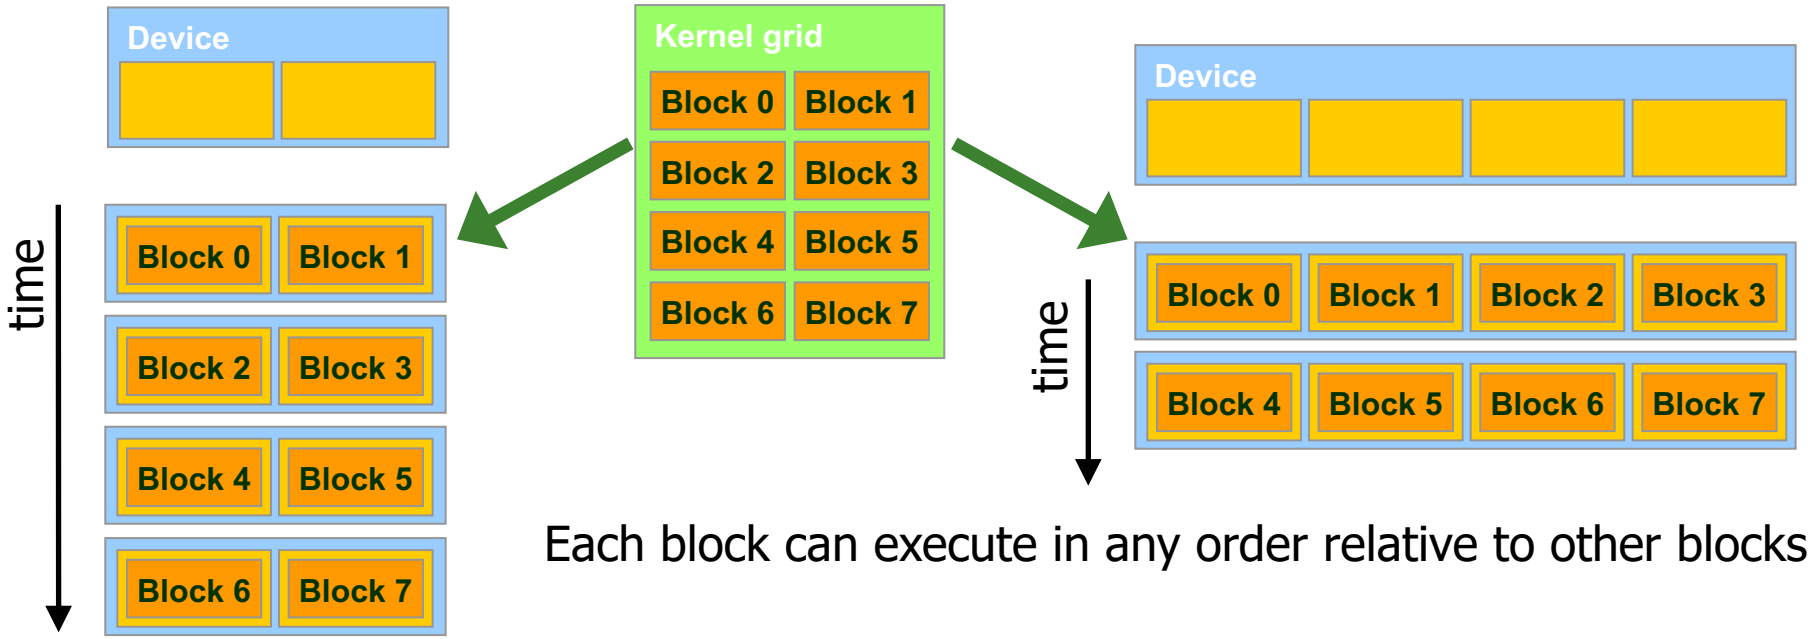
Vector Addition (III)

- We group threads into blocks



Transparent Scalability

- Hardware is free to schedule thread blocks



Each block can execute in any order relative to other blocks.

Slide credit: Hwu & Kirk

Launching a Grid

- Threads in the same grid execute the same function known as a kernel

- A grid can be launched by calling a kernel and configuring it with appropriate grid and block sizes

```
const unsigned int numThreadsPerBlock = 512;
const unsigned int numBlocks = N/numThreadsPerBlock;

vecadd_kernel<<<numBlocks, numThreadsPerBlock>>>(A_d, B_d, C_d, N);
```

Slide credit: Izzat El Hajj

Host Code Example: Vector Addition

```
void vecadd(float* A, float* B, float* C, int N) {

    // Allocate GPU memory
    float *A_d, *B_d, *C_d;
    cudaMalloc((void**) &A_d, N*sizeof(float));
    cudaMalloc((void**) &B_d, N*sizeof(float));
    cudaMalloc((void**) &C_d, N*sizeof(float));

    // Copy data to GPU memory
    cudaMemcpy(A_d, A, N*sizeof(float), cudaMemcpyHostToDevice);
    cudaMemcpy(B_d, B, N*sizeof(float), cudaMemcpyHostToDevice);

    // Perform computation on GPU
    const unsigned int numThreadsPerBlock = 512;
    const unsigned int numBlocks = N/numThreadsPerBlock;

    vecadd_kernel<<<numBlocks, numThreadsPerBlock>>>(A_d, B_d, C_d, N);
    // Copy data from GPU memory
    cudaMemcpy(C, C_d, N*sizeof(float), cudaMemcpyDeviceToHost);

    // Deallocate GPU memory
    cudaFree(A_d);
    cudaFree(B_d);
    cudaFree(C_d);
}
```

Slide credit: Izzat El Hajj

Sample GPU SIMT Code (Simplified)

CPU code

```
for (ii = 0; ii < 100000; ++ii) {
C[ii] = A[ii] + B[ii];
}
```

CUDA code

```
// there are 100000 threads
__global__ void KernelFunction(…) {
  int tid = blockDim.x * blockIdx.x + threadIdx.x;
  int varA = aa[tid];
  int varB = bb[tid];
  C[tid] = varA + varB;
}
```

Slide credit: Hyesoon Kim

Vector Addition Kernel

- It is preceded by the keyword `__global__` to indicate that it is a GPU kernel

- It uses special keywords to distinguish different threads from each other
  - Block index (`blockIdx.x`), block size (`blockDim.x`), thread index (`threadIdx.x`)

```
__global__ void vecadd_kernel(float* A, float* B, float* C, int N) {

    int i = blockDim.x * blockIdx.x + threadIdx.x;

    C[i] = A[i] + B[i];

}
```

Boundary Conditions

- What if the size of the input is not a multiple of the number of threads per block?
  - Solution: use the ceiling to launch extra threads then omit the threads after the boundary

```
const unsigned int numBlocks = (N +numThreadsPerBlock – 1)/numThreadsPerBlock;
```

- Kernel code

```
__global__ void vecadd_kernel(float* A, float* B, float* C, int N) {

    int i = blockDim.x*blockIdx.x + threadIdx.x;

    if(i < N) {
        C[i] = A[i] + B[i];
    }
}
```

Compilation

Indexing and Memory Access

- Images are 2D data structures
  - height x width
  - Image[j][i], where 0 ≤ j < height, and 0 ≤ i < width

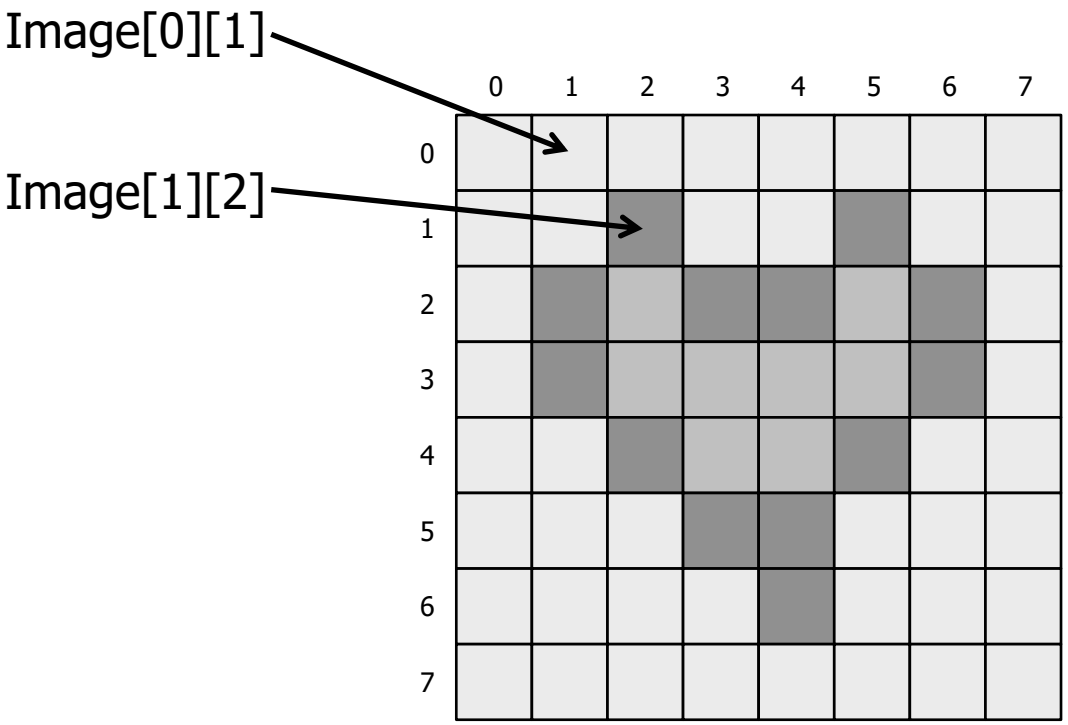

Image Layout in Memory

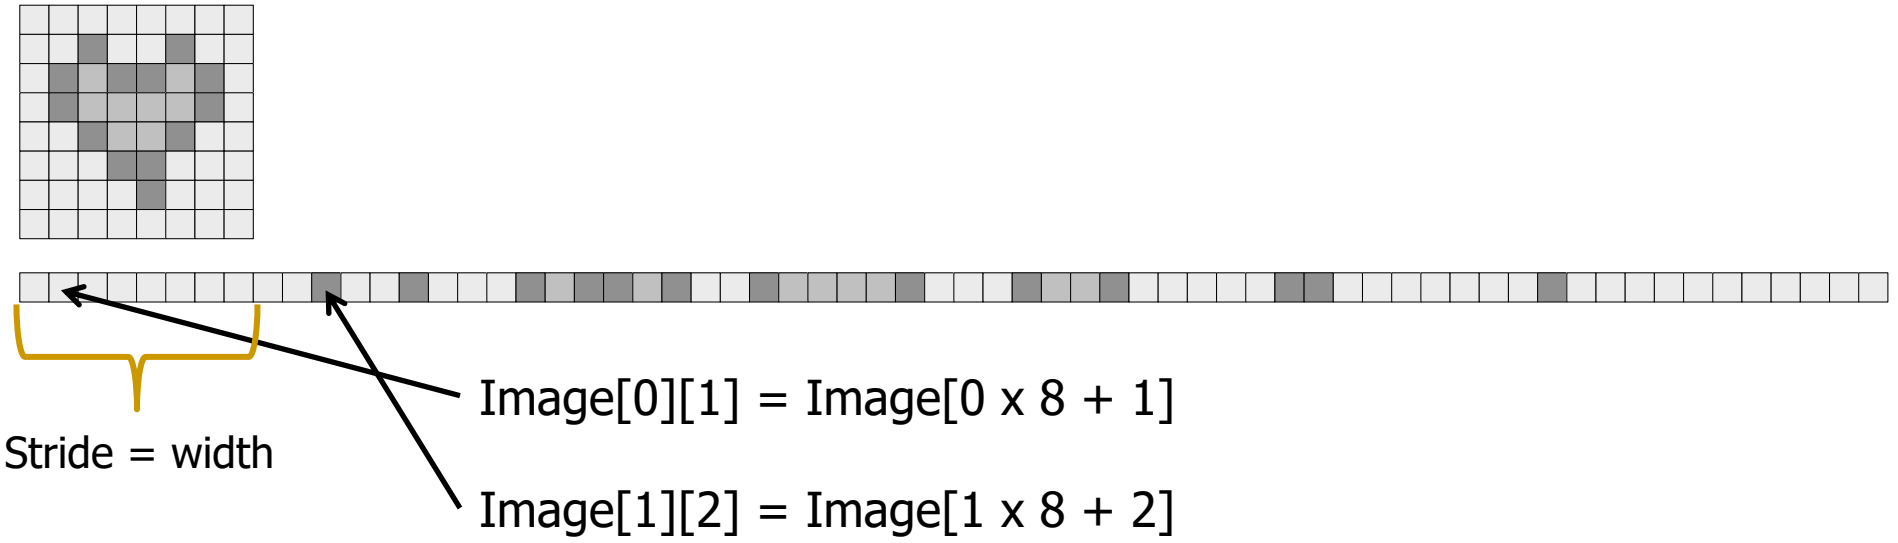
- Row-major layout
- Image[j][i] = Image[j x width + i]

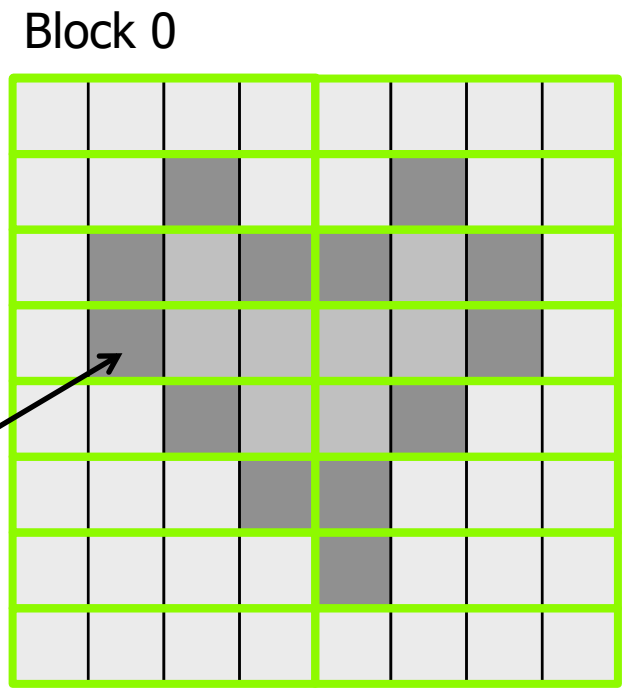


Indexing and Memory Access: 1D Grid

- One GPU thread per pixel
- Grid of Blocks of Threads
  - `gridDim.x, blockDim.x`
  - `blockIdx.x, threadIdx.x`

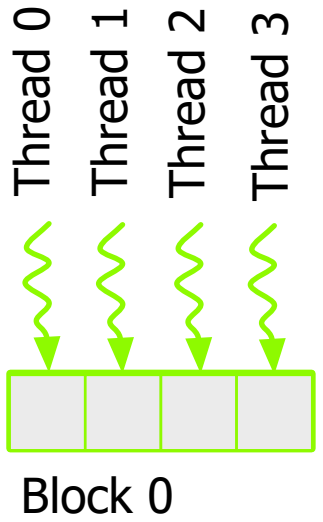
`blockIdx.x`

`threadIdx.x`



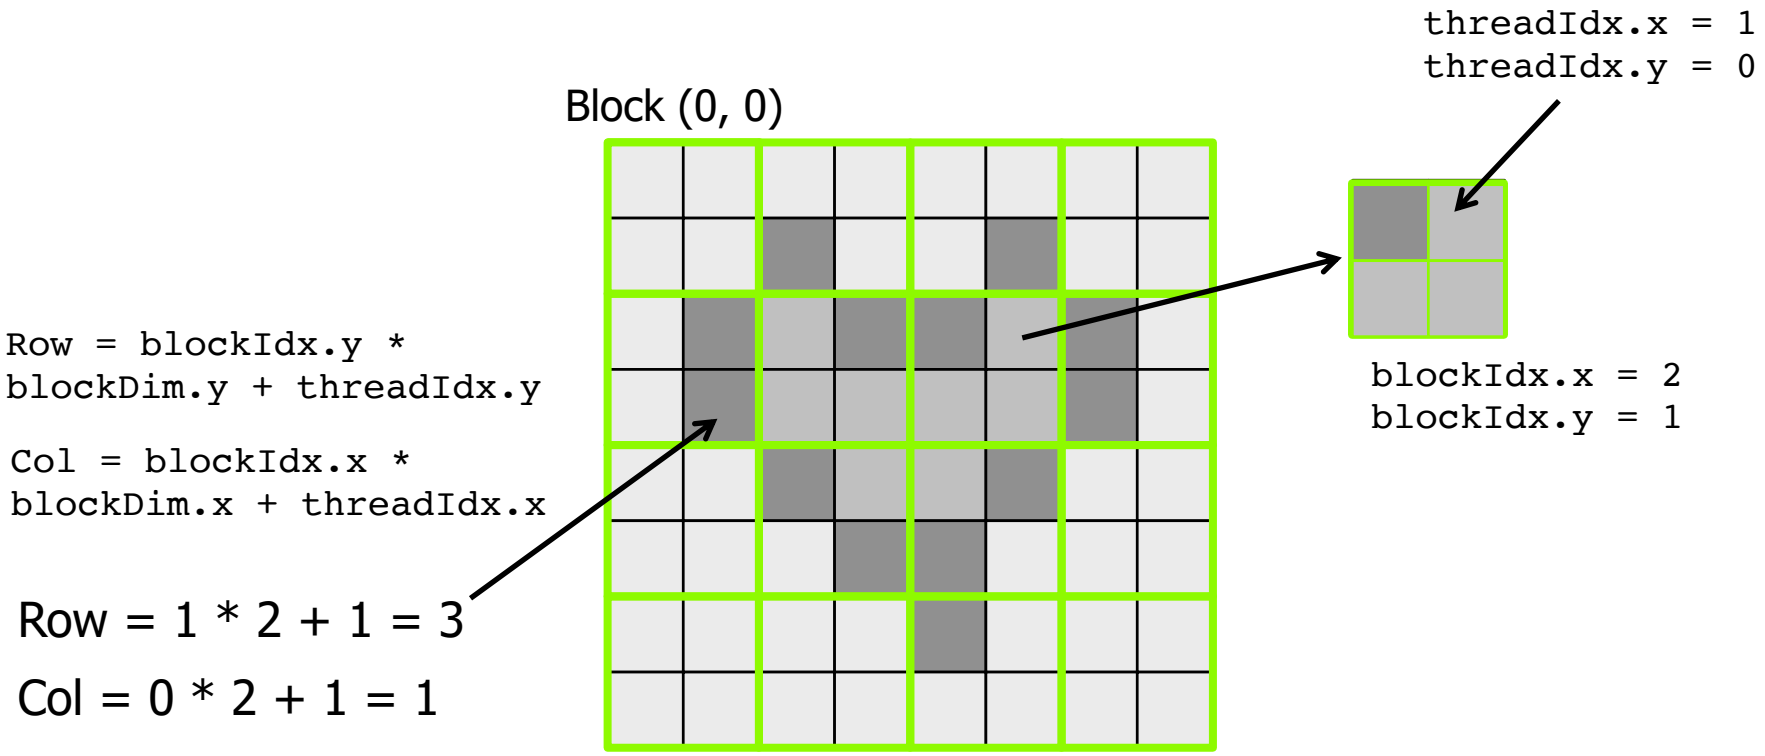
6 * 4 + 1 = 25

`blockIdx.x * blockDim.x + threadIdx.x`



Indexing and Memory Access: 2D Grid

- 2D blocks
  - `gridDim.x, gridDim.y`

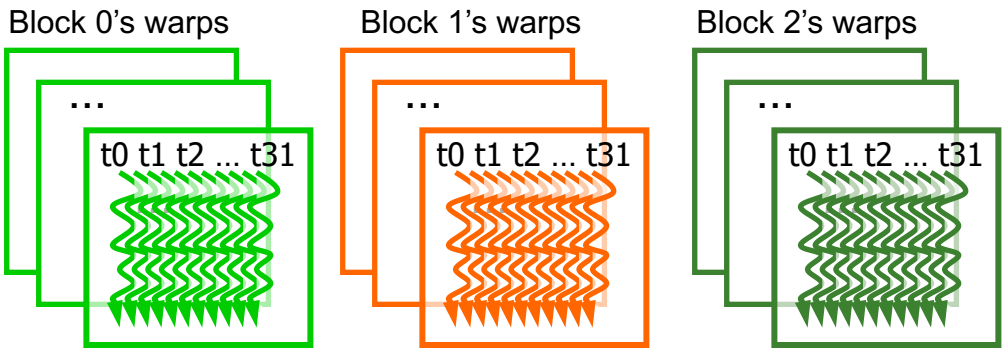


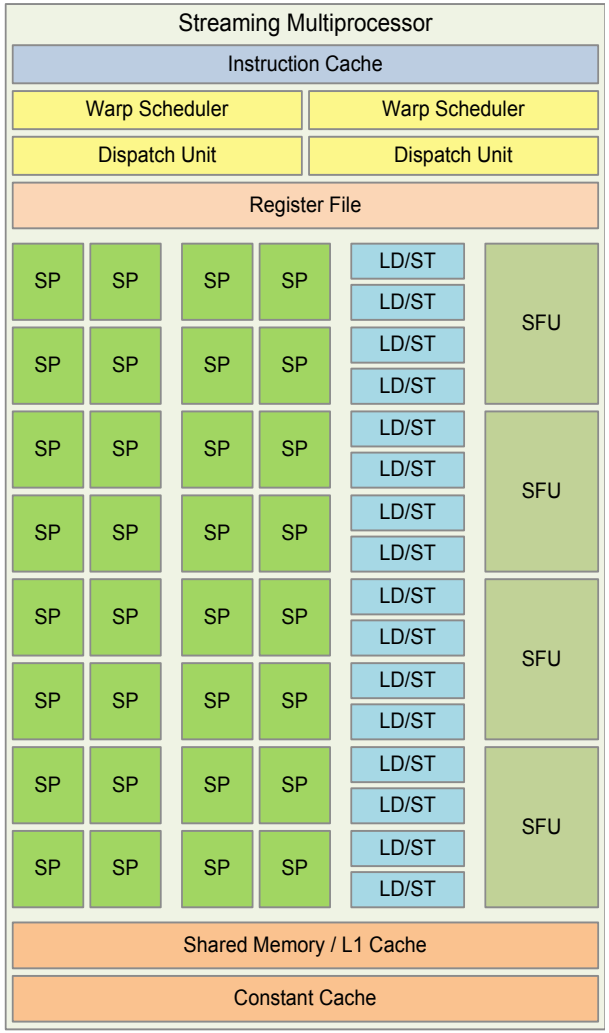
Image[3][1] = Image[3 * 8 + 1]

Recall: From Blocks to Warps

- GPU cores: SIMD pipelines
  - Streaming Multiprocessors (SM)
  - Streaming Processors (SP)

- Blocks are divided into warps
  - SIMD unit (32 threads)





NVIDIA Fermi architecture
